19. ABSTRACT (Continue on reverse if necessary and identify by block number) Wind tunnel test results on a typical projectile shape with small nose bluntness are reported. Flat and hemispherical nose tip results are shown in addition to sharp nose tip results. The effects of nose bluntness on static stability are shown to be negligible at both Mach 0.91 and 3.02. The effects of nose bluntness on Magnus force and Magnus moment were not large, but of sufficient magnitude to indicate that such bluntness should not be neglected in a numerical flow field computation.

SUMMARY

1. For purposes of computational modeling, the effects of nose bluntness cannot be ignored.

2. The effect of blunting the nose tip is to increase the Magnus force. No large or consistent effect of nose tip bluntness on yawing moment or side force center of pressure was observed.

3. The effect of nose tip bluntness on pitch plane force and moment data was found to be small.

4. The results of the present investigation are consistent with findings of Dolling's nose tip bluntness investigation.

5. The side force center of pressure data at small pd/V and small α are not considered reliable.

I. INTRODUCTION

A theoretical and experimental research program has been underway in the Launch and Flight Division of US Army Ballistic Research Laboratory (BRL), Aberdeen Proving Ground, MD, in recent years to provide the capability of predicting projectile aerodynamics. The direction of the predictive capability is generally toward the use of modern finite-difference computational techniques. The primary objective of the experimental program is to obtain data for comparison with computations. The ogive-cylinder-boattail shape of Figure 1 was chosen because a substantial amount of experimental and computational data already exist for this shape which is typical of modern low drag shell.

The three nose tip configurations are shown in Figure 2; the flat nose tip is typical of a projectile fuze meplat. Parabolized Navier Stokes computations are being used for supersonic flow field computations and time-dependent Navier Stokes Computations are being used for transonic flowfields, including base flows. These computations can often be facilitated by the use of a sharp nose tip approximation or by a spherical nose tip approximation but only if no significant error is introduced.

II. EXPERIMENT

1. MODELS AND INSTRUMENTATION

The geometry of the ogive-cylinder-boattail configuration (SOCBT) is shown in Figure 1. The ogive-cylinder (SOC) is identical except that the boattail is zero degrees. The Model was equipped with a boundary layer trip which was located 1.15 caliber from the tip of the sharp nosed configuration for the $M = 3.02$ test runs. The boundary layer trip was not used for the transonic test runs. Three nose tips were tested as seen in the shadow-graph of Figure 2. The height of the flat and spherical portions of the nose tip was 0.1 caliber at the intersection of the ogive. The model was equipped with an air turbine system for spinning the model to approximately 700 rps as required for the Magnus test runs. An internal strain-gage balance capable of measuring normal force, pitching moment, side force, and yawing moment was supplied by the Naval Surface Weapons Center (NSWC), Silver Spring, MD.

2. WIND TUNNELS

The tests were conducted in the NSWC Tunnel No. 2 which is a $0.41 \times 0.41\text{m}$ (16 x 16 inch) cross section, horizontal tunnel with an open jet test section capable of operation over a Mach number range of 0.3 to 5.02 with supply pressures ranging from 0.5 to 15 atmospheres. The tunnel is capable of intermittent (blowdown) or continuous operation with a higher Reynolds capability for the intermittent mode. Mach number changes are made by replacing the two-dimensional nozzle block units -- each nozzle block provides one distinct Mach number.

3. PROCEDURES

Supply pressure for the Mach 0.91 test runs was set at one atmosphere and the supply temperature was typically 300 k (80 deg F). For the Mach 3.02 test runs, supply pressure was set at 138×10^3 kPa (20 psia) and the supply temperature was typically 306 k (90 deg F). These conditions provided Reynolds numbers of 4.5×10^6 at Mach 0.91 and 2.2×10^6 at Mach 3.02 based on the model length. Data for the static stability phase of the program was acquired by pitching the model from -5 to +15 degrees and recording data continuously at the rate of 10 samples per second -- this procedure provided approximately 80 points for each pitch run. Data for the Magnus phase of the test programs were acquired by setting the model at a given angle of attack, applying turbine air to bring the model up to the desired spin rate, cutting off the turbine air supply and allowing the spin rate to decay to zero. Data were recorded during the spin down at the rate of 10 samples per second which typically yielded 350 samples at Mach 0.91 and 700 samples at Mach 3.02.

The static stability data, as a function of angle of attack, and the Magnus data, as a function of pd/V , data were fitted with 5th order polynomial curves to facilitate handling and interpretation of the data. The 5th order curve fit was usually more than adequate to describe the data variations. Figure 3 is a typical set of side force data for $M = 0.91$ and illustrates the random noise level of the data; also, it is seen that the data do not pass through the origin. The zero term of the polynomial curve fit was discarded in order to force the data through the origin as dictated by theory. Discrete values of C_Y and C_{n_p} were obtained from the curve fitted data at a $pd/V = 0.5$ for Mach 0.91 and $pd/V = 0.2$ for Mach 3.02. The discrete values were then divided by the respective values of pd/V to obtain the coefficients of C_Y and C_{n_p} . For plots of C_Y and C_{n_p} , data were not forced through the origin.

NOTE: Curve fitted data for moment coefficients are for a cg location 3.5 cal. from the nose tip (2.5 cal. from the base). Plotted moment coefficient data are for a cg location 3.6 cal. from the nose tip (2.4 cal. from the base)

III. RESULTS

A complete set of Magnus data is given in tables 1 through 4 in the form of polynomial coefficients:

$$C_Y = a1*(pd/V) + a2*(pd/V)**2 + a3*(pd/V)**3 + \dots$$

$$C_{n_p} = b1*(pd/V) + b2*(pd/V)**2 + b3*(pd/V)**3 + \dots$$

Figures 4-7 show the effects of nose bluntness on normal force and center of pressure. For the SOC shape at $M = 0.91$, normal force is not affected and the center pressure variation is less than 0.1 caliber. For the SOCBT at $M = 0.91$, normal force is not affected but the center of pressure behavior between -5 and +5 degrees seems questionable. The variation of approximately 0.2

calibers in X_{cp} may be reasonable but the asymmetry about $\alpha = 0^\circ$ is not expected. The asymmetry is consistent for all three nose tips which suggests a correct measurement. The asymmetry may be a hysteresis effect caused by tunnel wall interference. At $M = 3.02$, there are no measurable effects of nose bluntness on normal force or center of pressure for either shape. The centers of pressure are seen to be symmetric about $\alpha = 0^\circ$ for $M = 3.02$.

Figures 8-9 show the effect of angle of attack on side force efficient for the sharp nose tip. For $M = 0.91$, the variation with angle of attack shows a consistent behavior and the effect of the boattail is seen to increase the magnitude of the side force. At $M = 3.02$, the magnitude of the side force is slightly smaller on the boattailed configuration. It is also noticed at $M = 3.02$, Figure 9, that a positive side force exists at zero degree angle of attack which suggests a phenomenon such as a flow angularity in the wind tunnel. The incremental increases in side force with increasing angle are consistent which indicates that the data are biased by an amount equal to the side force values at zero degrees.

Figures 10-11 show the effects of nose bluntness on the side force coefficient at three degrees angle of attack. The effect of bluntness is generally seen to increase the magnitude of side force on both configurations both Mach numbers with the flat nose tip providing the largest effect. Yawing moment coefficient data are shown in Figures 12-13. The yawing moment coefficients on the SOC at $M = 0.91$ show the unusual non-linear behavior of initially decreasing with pd/V and then increasing at the higher values of pd/V . At all other conditions, the yawing moment increases nearly linearly with pd/V but there does not seem to be a consistent effect of nose bluntness. The side (Magnus) force centers of pressure are shown in Figures 14-15. Data at small pd/V do not appear too reliable but the effect of bluntness is generally to move the center of pressure forward. The effect of the boattail is to move the Magnus center of pressure aft at both Mach numbers.

Figures 16-21 provide a concise summary of all the Magnus data. Figures 16-17 show a definite influence of nose bluntness on Magnus force coefficient with the bluntness increasing the magnitude of the coefficients. Figure 17 (SOCBT) shows the non zero Magnus force coefficient at zero degree alpha and also the general bias of the data as mentioned above in conjunction with Figure 9. Magnus moment coefficients are shown in Figures 18-19 and do not show a definite trend with respect to nose bluntness. Magnus centers of pressure are shown in Figures 20-21 and are seen to be erratic at small angles of attack. The erratic behavior is a result of the bias mentioned above. The centers of pressure appear to be reliable for angles of attack greater than two degrees and do not change significantly with angle of attack. At the smaller angles of attack, the effect of bluntness is to move the center of pressure forward. As mentioned above, the effect of the boattail is to move the center of pressure aft.

Effects of nose bluntness on surface pressures and boundary layer parameters at Mach 3.0 were recently reported by Dolling, et al.¹ The results were for non-spinning axisymmetric shapes, characteristic of projectiles. Dolling concluded that "the distance for completion of entropy wake effects on surface pressure distributions is small. Even with significant tip blunting ...". Also concluded was that "...tip bluntness has a strong influence on the development of all boundary-layer properties." If the surface pressures

are not significantly affected by nose tip bluntness, normal force and pitching moments should not be greatly affected. Results of the present investigation showed that normal force, pitching moment, and center of pressure were not affected by the two types of bluntness tested. Since the Magnus effect is a function of the boundary layer characteristics, it could be expected, according to Dollings findings, that nose tip bluntness would affect Magnus results. Results of the present investigation show that Magnus results are affected by nose tip bluntness.

LIST OF SYMBOLS

C_m	= pitching moment coefficient, cg 2.4 cal from base
C_N	= normal force coefficient
C_n	= yawing moment coefficient, cg 2.4 cal. from base
C_{n_p}	= $C_n/(pd/V)$, $pd/V = 0.5$ at $M = 0.91$; $pd/V = 0.2$ at $M = 3.02$
C_Y	= side force coefficient
C_{Y_p}	= $C_Y/(pd/V)$, $pd/V = 0.5$ at $M = 0.91$; $pd/V = 0.2$ at $M = 3.02$
d	= model diameter at a cylinder cross section
p	= model spin rate, radians/sec
pd/V	= dimensionless spin rate
S	= reference area, $(3.1416)*d*d/4$
V	= free-stream velocity
x_{cp}	= C_m/C_N , normal force center of pressure
y_{cp}	= C_n/C_Y , side (Magnus) force center of pressure

USER EVALUATION SHEET/CHANGE OF ADDRESS

This Laboratory undertakes a continuing effort to improve the quality of the reports it publishes. Your comments/answers to the items/questions below will aid us in our efforts.

1. BRL Report Number _____ Date of Report _____
2. Date Report Received _____
3. Does this report satisfy a need? (Comment on purpose, related project, or other area of interest for which the report will be used.) _____

4. How specifically, is the report being used? (Information source, design data, procedure, source of ideas, etc.) _____

5. Has the information in this report led to any quantitative savings as far as man-hours or dollars saved, operating costs avoided or efficiencies achieved, etc? If so, please elaborate. _____

6. General Comments. What do you think should be changed to improve future reports? (Indicate changes to organization, technical content, format, etc.) _____

	_____ Name
	_____ Organization
CURRENT ADDRESS	_____ Address
	_____ City, State, Zip

7. If indicating a Change of Address or Address Correction, please provide the New or Correct Address in Block 6 above and the Old or Incorrect address below.

	_____ Name
	_____ Organization
OLD ADDRESS	_____ Address
	_____ City, State, Zip

(Remove this sheet along the perforation, fold as indicated, staple or tape closed, and mail.)
